

The splitter is full of messy branch pipes

Overview

You can't really "split" liquids, they mostly go wherever pressure and pipes allow them to. The mark 2 pipes (600/min) seem to not work correctly. Originally posted by Migz - DH: Before doing anything else, I suggest rethinking the plan to use 600 of any fluid in one line. The mark 2. Using splitters, you have all your material come in one side, and when they enter a splitter, it takes turns using the next conveyor. Followed by an example of how I use this in my build; 1200 hours in. The setup is compact and can be expanded easily.

The splitter is full of messy branch pipes

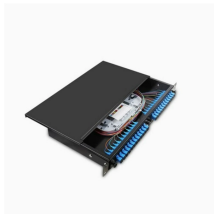

With pipe crosses, excess from line one does NOT go to line two. The solution is simple. Split your pipes like a bracket. With the bracket method, you can equalize each final connection. But like everything, ...

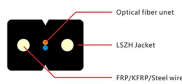

Provided you're producing enough to satisfy the needs of all of the machines hooked into each of these pipes, there's no reason to try and balance them--just hook them up into a manifold and call it a day.

Manifold refers to a fill method where Conveyor Splitters or Conveyor Mergers are aligned in a series (that is, one after another), usually parallel to the arrangement of buildings. The setup is compact and ...

You see some getting through because as far as steel pipes go, it's functioning as a normal splitter. Since the splitter defines steel pipes in one direction, it will refuse to allow pipes to go ...

A Smart or Programmable Splitter allows you to define which output of a splitter a product can be directed. Using the overflow feature of the splitter allows for excess product to be directed ...

In this video, I show how you can choose to go left or right into a new pipe, and also how multiple pipes can be merged into a single one.

The longer the pipe and the more flow it can handle, the greater the chance of getting sloshing, where the water bounces back and forth. When it bounces back to the water pump (or ...

A pipeline manifold, a.k.a pipe header, is a kind of arrangement where a "main" pipe is connected to a series of secondary pipes. It can serve either as a fluid distributor or a fluid collector.

The almost universal fix for the issue you're having (assuming your factory is running as it needs to otherwise) is to delete all pipe segments that run through a splitter and rerun them from ...
